

## Sample Size & Power for Comparing Proportions

Three approaches:

1.  $n$  needed to estimate given effect with margin of error  $m$  (not covered in Ch 17)
2.  $n$  needed to test  $H_0$  at given  $\alpha$  and power
3. Power of test of  $H_0$  under given conditions

33

## Sample Size Requirements for Comparing Proportions

Depends on:

- $r$   $\equiv$  sample size ratio =  $n_1 / n_2$
- $1-\beta$   $\equiv$  power (acceptable type II error rate)
- $\alpha$   $\equiv$  significance level (type I error rate)
- $p_1$   $\equiv$  expected proportion, group 1
- $p_2$   $\equiv$  expected proportion in group 2, or expected effect size (e.g.,  $RR$ )

## Calculation

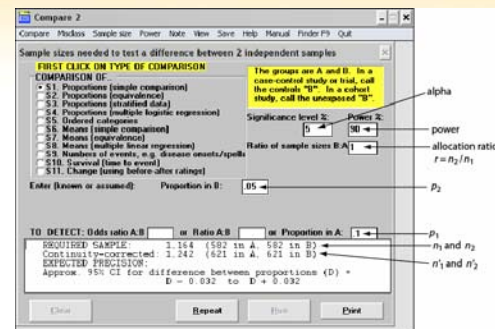

- Formulas on pp. 396 – 402 (quite complex)
- In practice  $\Rightarrow$  use tables or (better yet) computer programs
